CTI TECH TIP

Modern Suspension Alignment Systems

Today's modern vehicle suspensions require a precise four-wheel alignment that can only be achieved using a modern alignment system. This applies to both front and rear wheel drive vehicles. Sometimes problems can arise from something as small as driving over a pothole, or grazing over a curb. A vehicle will need the alignment checked when noticeable steering problems or uneven tire wear patterns occur.

Restoring a vehicle to proper alignment can be difficult when a technician does not properly understand that there is more to do than setting the angles we are familiar with: caster, camber and toe. For example, a vehicle may have struck a curb and bent a steering knuckle slightly. If the vehicle is returned to within specifications without replacing the bent steering knuckle, it may drive okay in a straight line, but produce handling and tire wear issues when cornering.

If alignment angles need a major correction, it may be an indication that the vehicle symmetry has changed. It is necessary to **focus** on the measurements that will indicate this condition **before** proceeding. If the vehicle is **not** symmetrical, setting the alignment angles to specifications most likely will not correct handling and tire wear issues.

Vehicle dimensioning supplies technicians with information on possible frame or body damage. Frame or body straightening may be needed to correct vehicle symmetry problems. Axle or frame problems will have a direct effect on alignment readings including: **caster, camber and thrust angle**. If there is an excessive problem with these angles, make sure to **check** symmetry measurements to determine if the vehicle is tracking properly. There are six

different measurements that refer to vehicle symmetry that we will cover. Vehicle symmetry measurements include: **setback, wheelbase, track width front, track width rear, track width side set and diagonal offset**. Specifications for these types of measurements are normally not given, but symmetry from side to side is preferred. The steering axis **inward** toward the center of the vehicle when compared to true vertical and is viewed from the front of the vehicle. SAI may also be known as **kingpin inclination**.

Steering axis inclination has three primary functions. Like caster, SAI promotes steering returnability and directional stability. Steering axis inclination also allows for the use of smaller camber angles to maximize traction during turns while maintaining decent tire wear. SAI helps reduce the influence of changing road surfaces on vehicle control by increasing the overall stability of the steering and suspension system.

Included angle is a direct indication of the spindle condition and is very helpful during the diagnosis of damaged components. If the spindle is **OK**, then the included angle should be correct. When included angle specifications are not available, the correct included angle value can be calculated by adding the camber and steering axis inclination angles. Positive camber results when an included angle is larger than the steering axis inclination angle. Negative camber results when the included angle is less than the steering axis inclination. Steering axis inclination and included angle should be considered any time the vehicle's primary alignment angles do not reveal the root cause of a handling or tire wear issue, or no apparent damage can be seen, but a handling issue is still present.
